Case Study: Filling census gaps in Afghanistan

WorldPop

High-resolution
population mapping in
Afghanistan 2017/18

Background

- ❑ Last census conducted in 1979; insecurity prevented a recent one; existing estimates based on 1979 baseline population;
- ❑ From 2011-2017 the CSO conducted a form of rolling census, the Socio-Demographic and Economic Survey (SDES) which included enumeration for 50% of households (the survey covered 12 of 34 provinces);
- ❑ Challenge: Lack of reliable current disaggregated population data at provincial, district level;
- ❑ President Ghani requested UN to assist CSO in estimating spatially disaggregated population data - Collaborative partnership including Government, UNFPA, WorldPop

Stages of the census cycle

Census cartography

Pilot census cartography

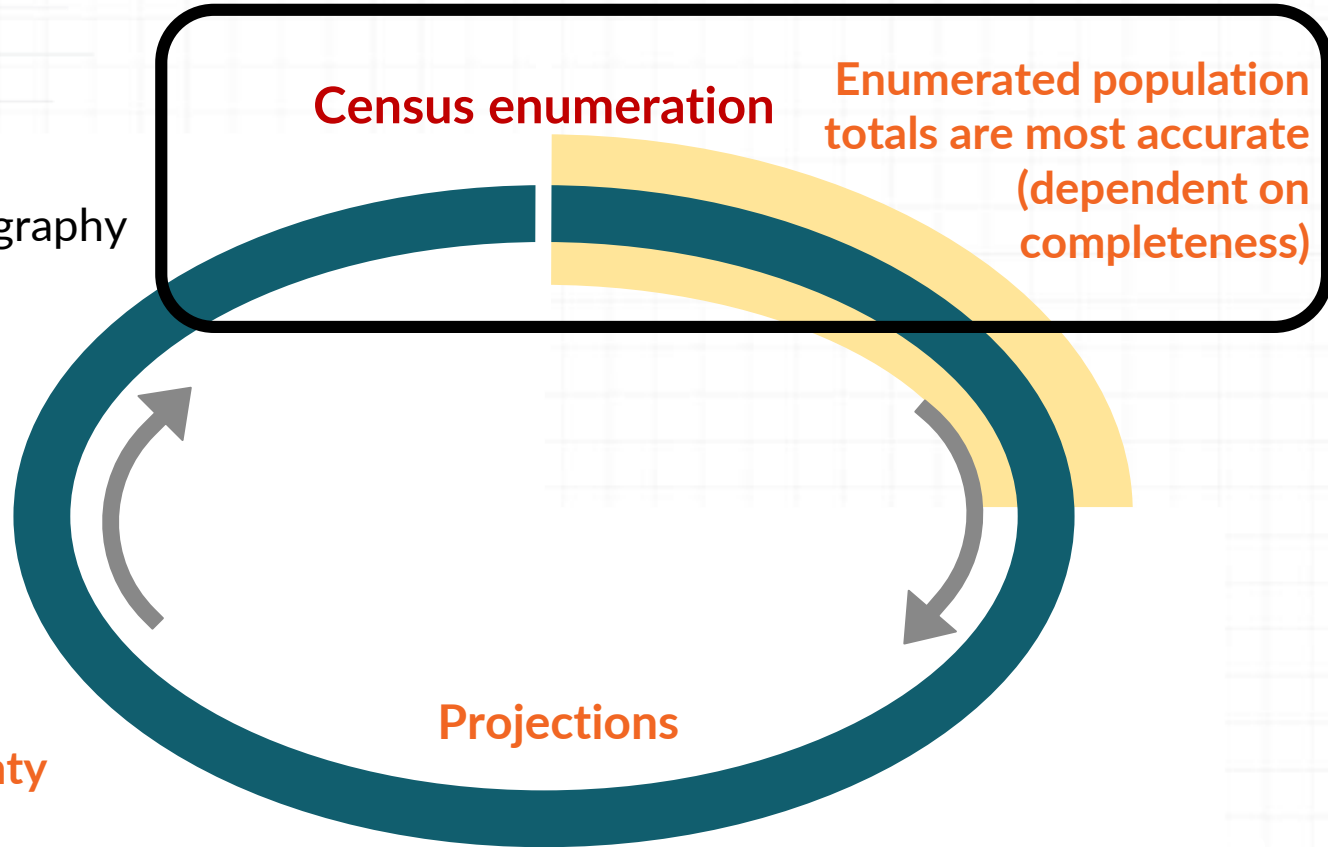

As time from the census elapses, increasing uncertainty in projections

Census enumeration

Enumerated population totals are most accurate (dependent on completeness)

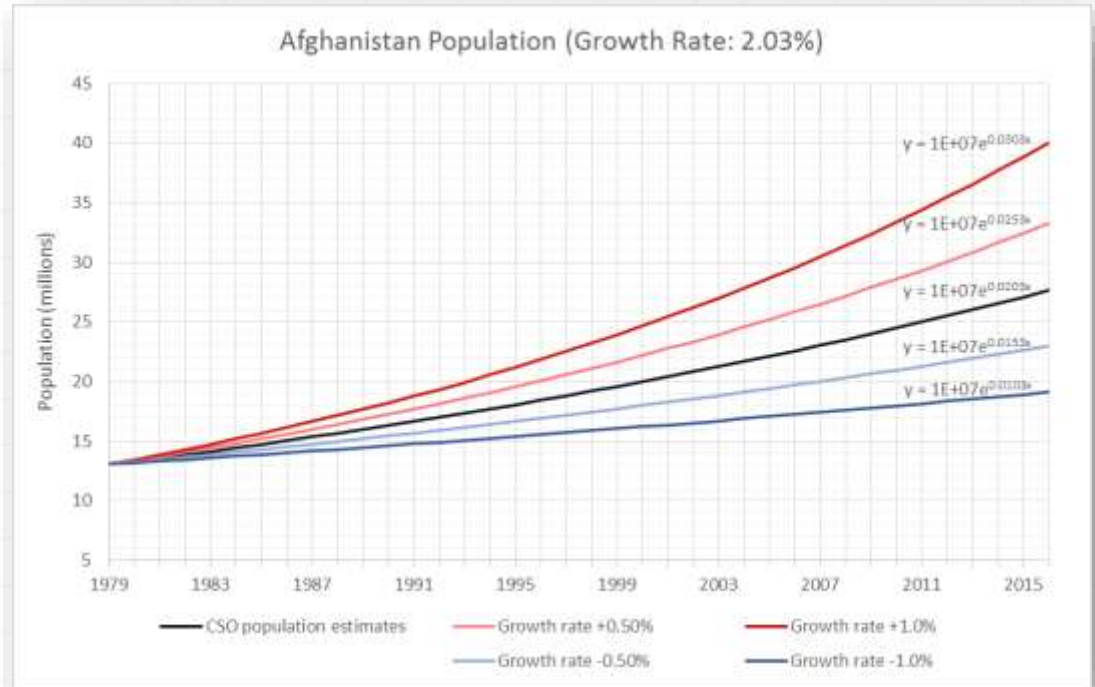

Projections

Intercensal period

Existing CSO estimates

- Existing estimates based on 2.03% growth rate from 1979 baseline
- Significant differences with recently gathered SDES numbers (typically underestimates)
- Analyses of newer data suggest that recent growth rates are more likely to be 3% or higher

Afghanistan: Project aims

- Estimate population counts at enumeration area (EA), district, province and national levels and associated measures of uncertainty;
- 100m x 100m gridded population estimates;
- Estimates of the age/sex structure of the population and associated measures of uncertainty
- Co-development with CSO and capacity strengthening

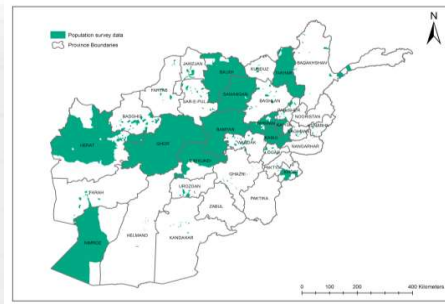

How does the population estimation process work?

Population estimation & mapping process

1. Enumerate population with ground-based surveys in defined areas
2. Predict population in un-surveyed areas
3. Spatial disaggregation of population estimates

We want to....

- *Estimate population density and total in each EA (with confidence intervals)*
- We have population density and total data for some EAs, but not all
- We do have data on factors related to populations in all EAs from satellites and other geospatial data

Example geospatial datasets

Number of compounds & area settled

Vegetation index

Night-time lights

Slope

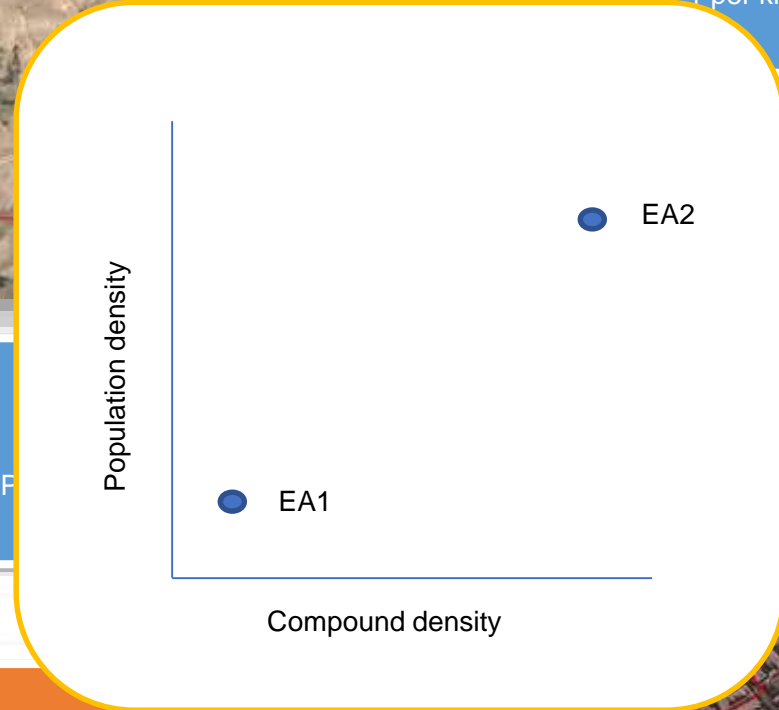

- >100 geospatial layers
- Sourced from across ministries, agencies and companies
 - Complete national coverage
 - Recent acquisition
 - Significant effort in checking, cleaning, harmonizing
- Processed to extract indicators likely to be predictive of population distributions and densities

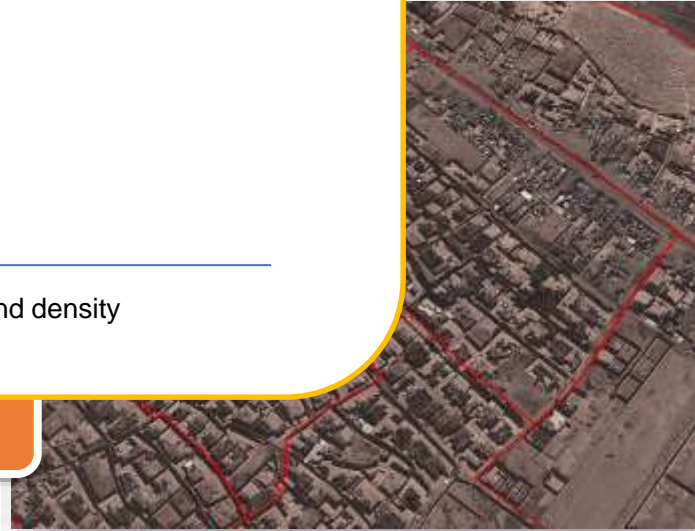

EA 1
Pop count: 1,000
Pop density: 1 per kmsq

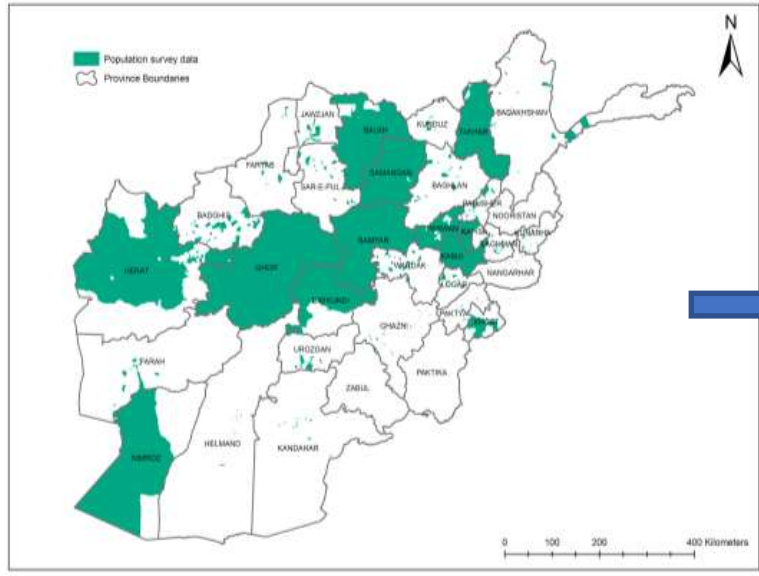

low

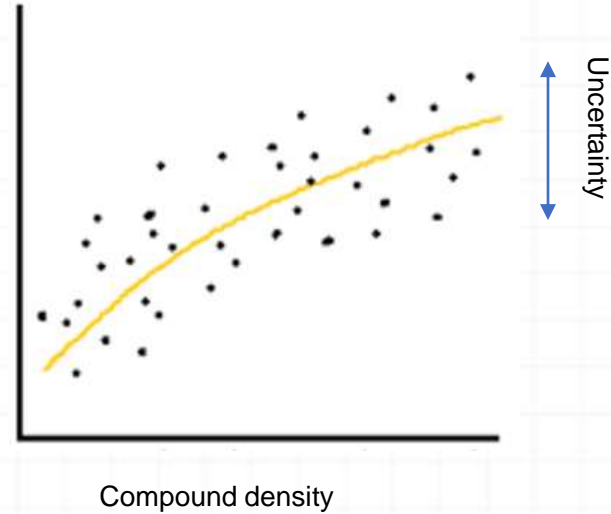

Compound density = high

What about other EAs where we have population data?

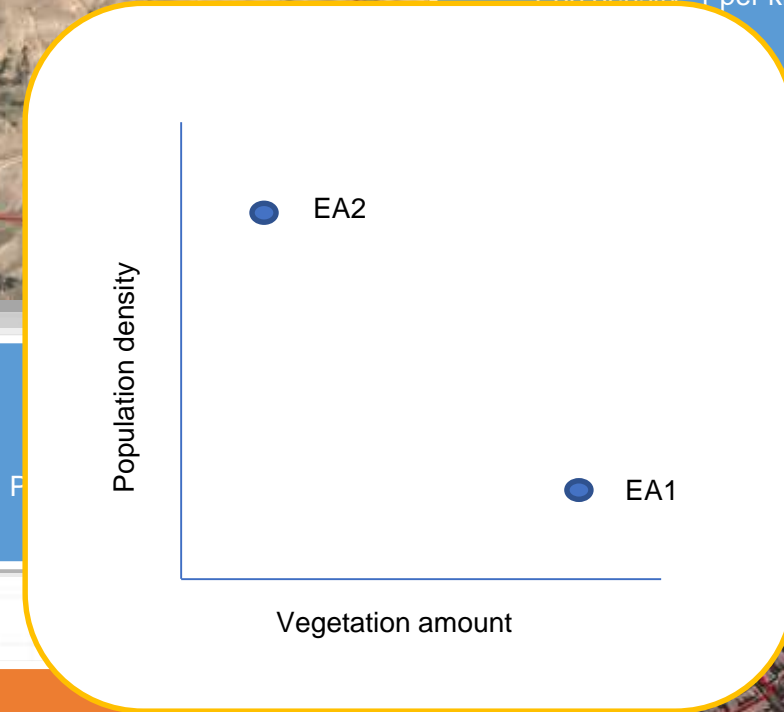

Population density

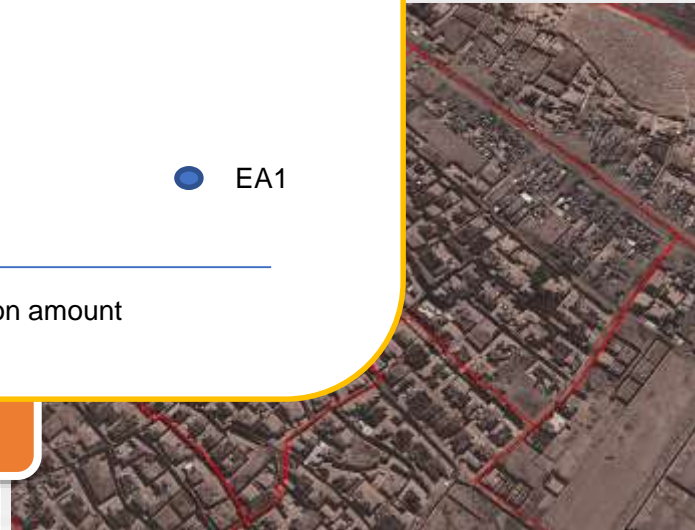

EA 1
Pop count: 1,000
Pop density: 1 per kmsq

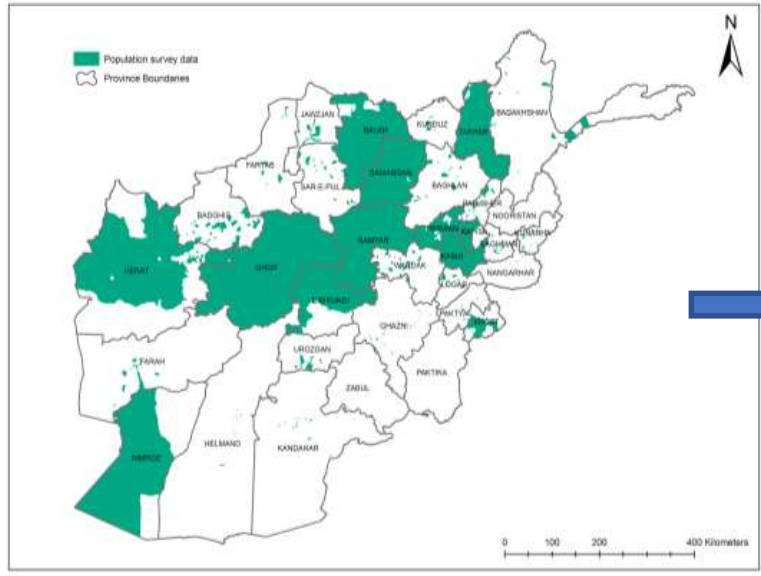

high

Vegetation amount =low

What about other EAs where we have population data?

Population density

Vegetation amount

Distance from urban area = high

Compound density = low

Mean slope gradient = high

Nightlights brightness = low

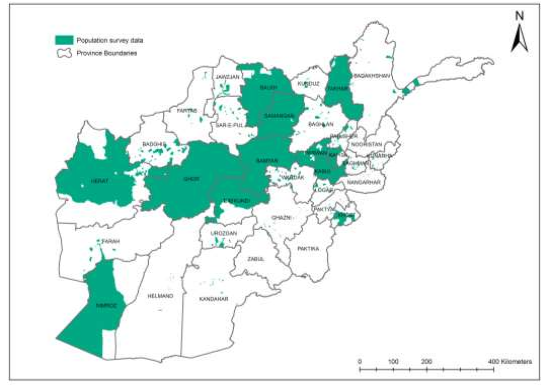

Distance from urban area = low

Compound density = high

Mean slope gradient = low

Nightlights brightness = high

Distance from urban area

Compound density

Mean slope gradient

Nightlights brightness

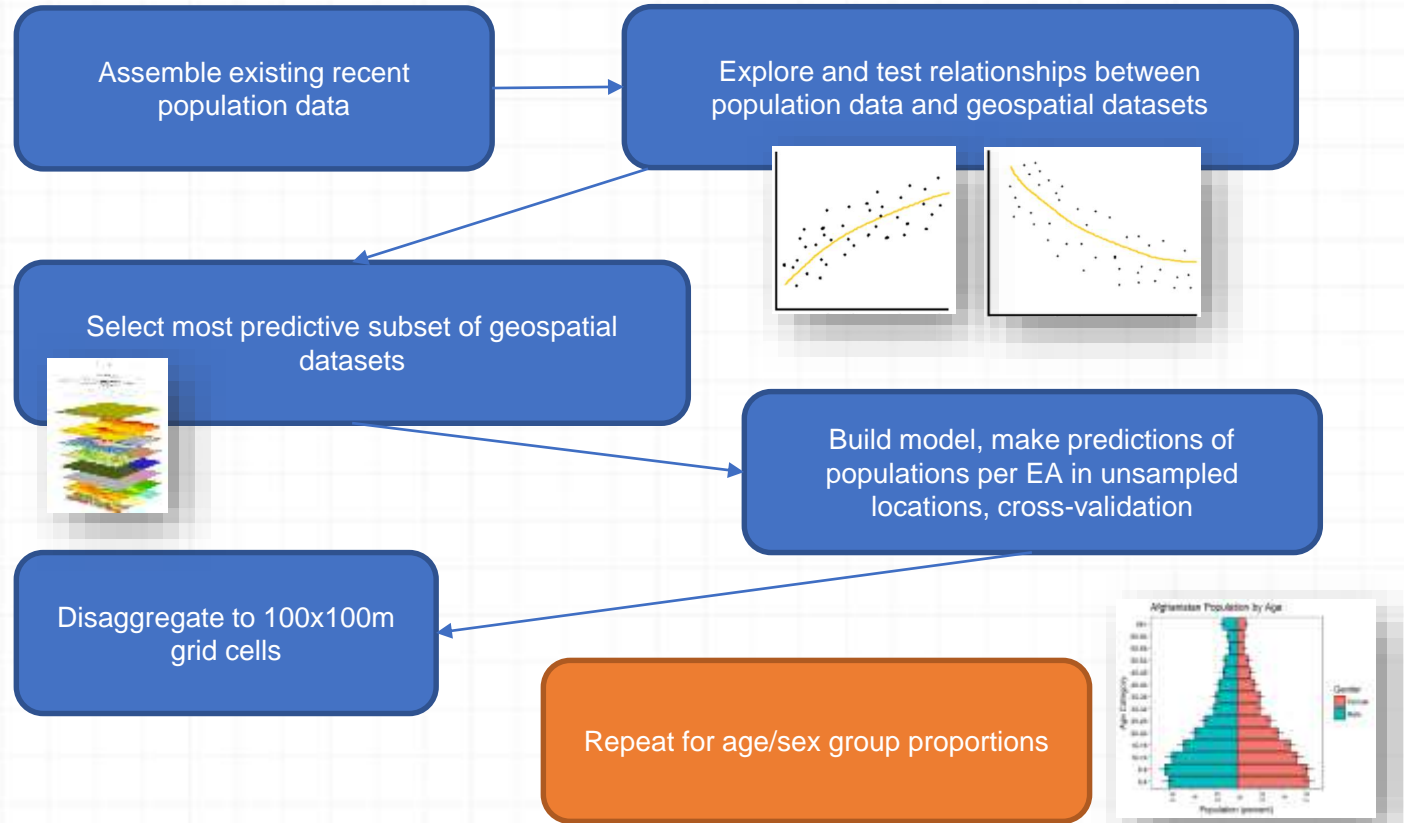

EA 3
Pop count: ?
Pop density: ? per kmsq

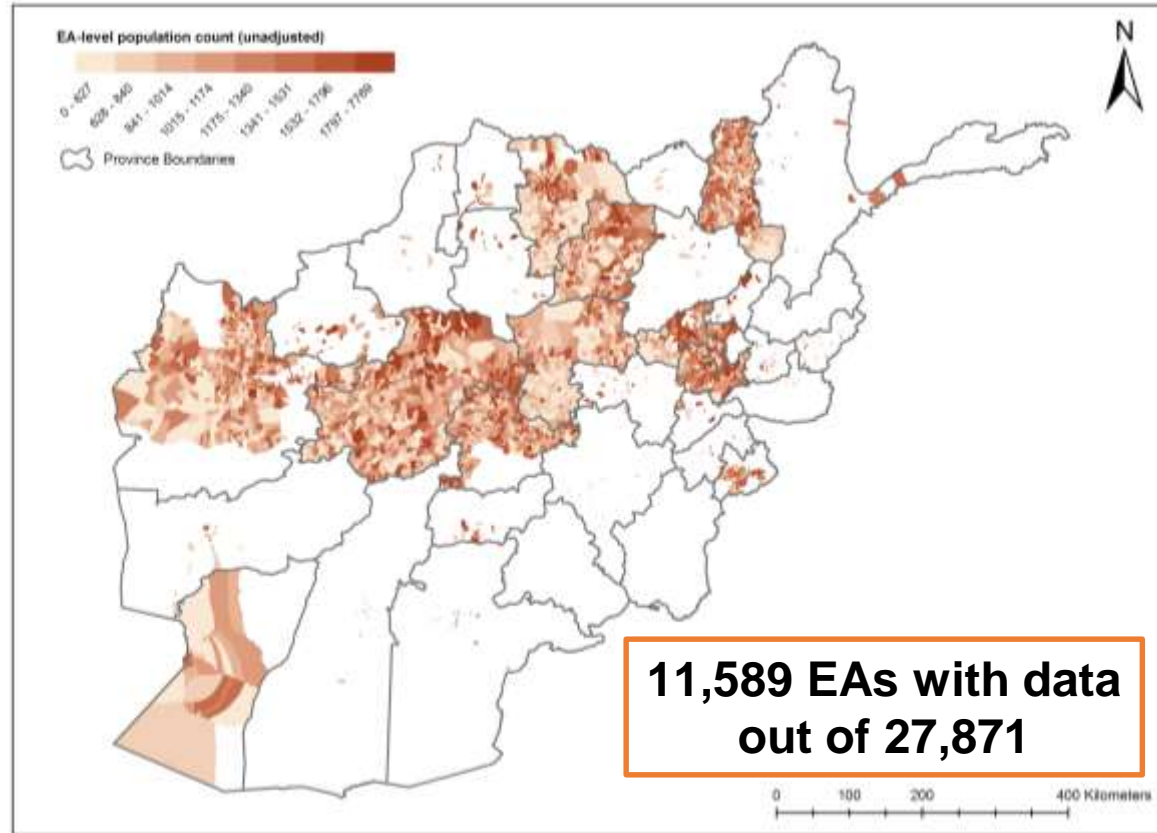

EA 3
Pop count: 350 (95% range =
300-400)
Pop density: 10 per kmsq (95%
range = 7-13)

Population estimation steps

Implementation for Afghanistan

Existing recent data

Finding the strongest predictors

Selected geospatial variables

Number of residential compounds

Compound density

Distance from edge of urban areas

Mean slope

Mean average distance between compounds

Minimum distance from a village

Maximum nightlight brightness

Fragmentation of settled area

Area of the EA

Vegetation amount

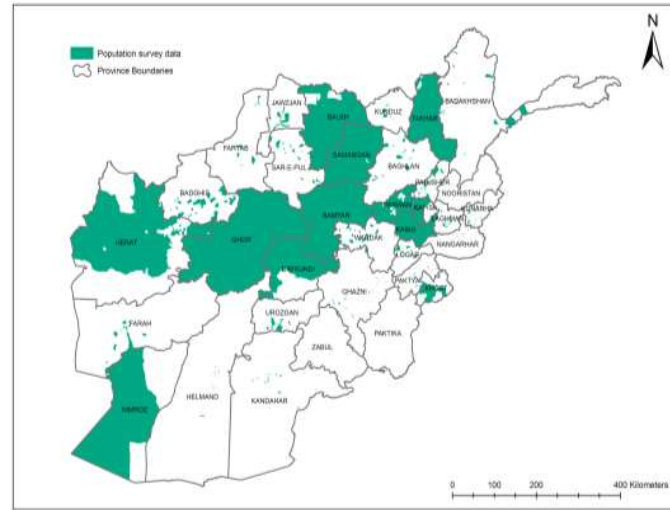

Training and testing

- Multiple model types and forms tested
- Selected the type and set of covariates that optimised predictive ability

Bayesian hierarchical spatial model:

- multiple model forms
- accounts for spatial relationships
- measures of uncertainty

- 10-fold cross-validation
 - 11,589 EAs with data
 - Split randomly into 10 groups
 - Further subdivided into training and testing sets
 - Mean observed vs prediction stats

Cross-validation: EA level

Correlation: 0.61

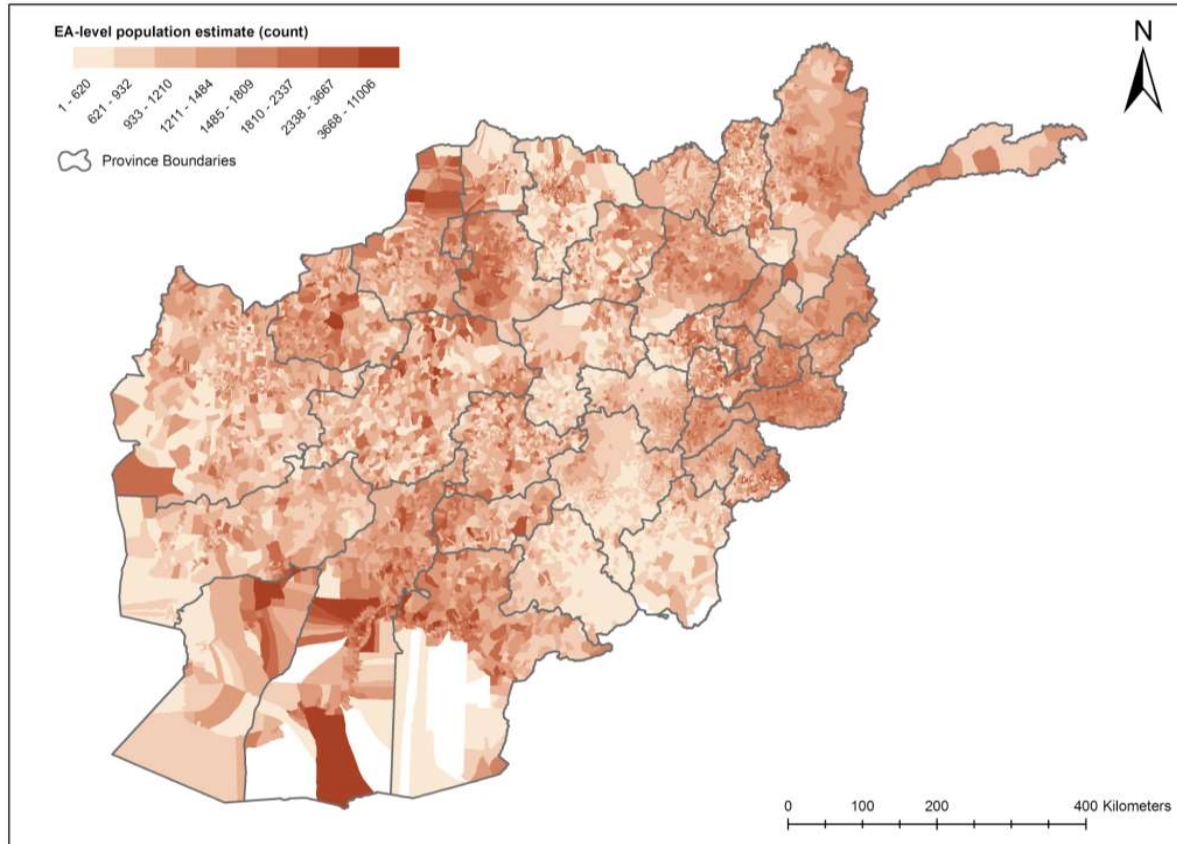

Mean population
weighted error 22%

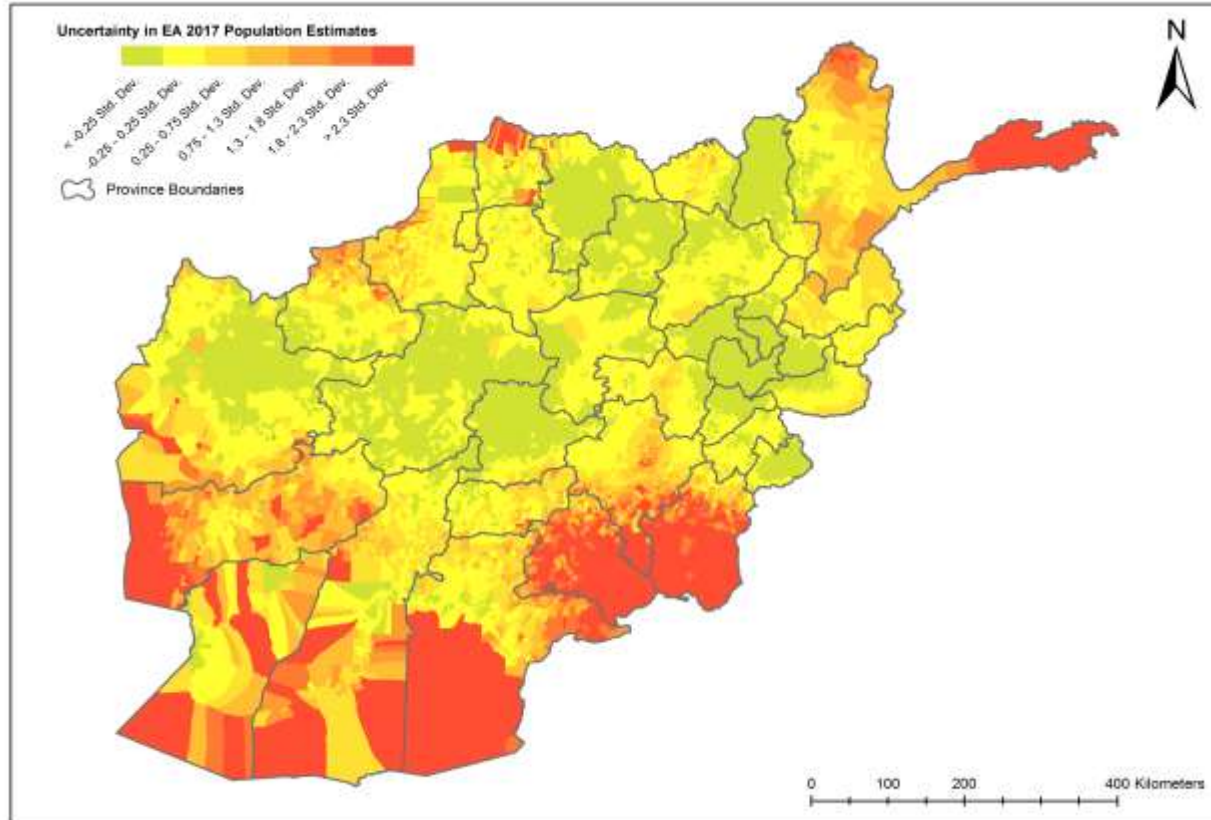

Accuracy assessment: District and Province level

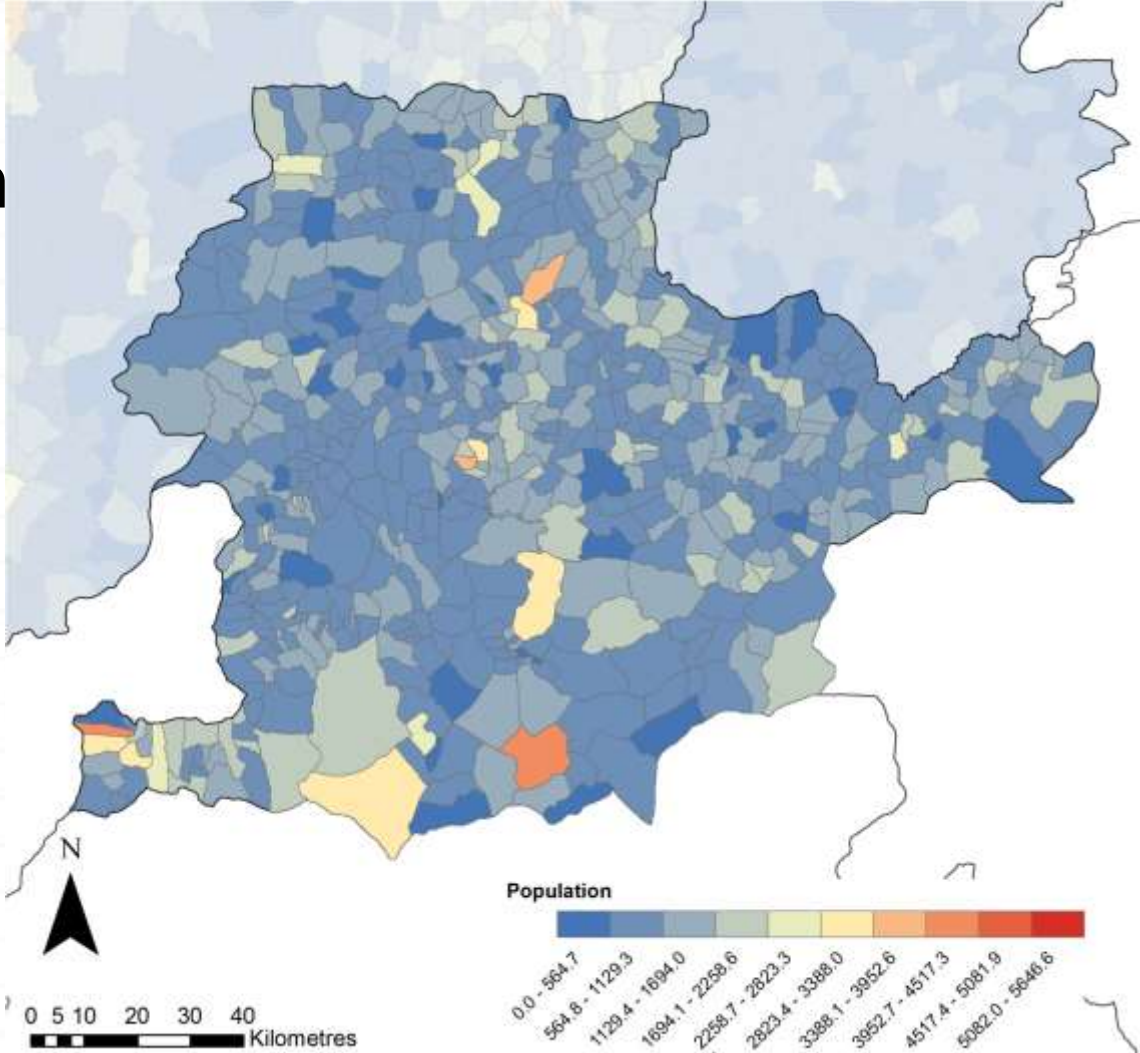

Outputs: EA counts and estimates

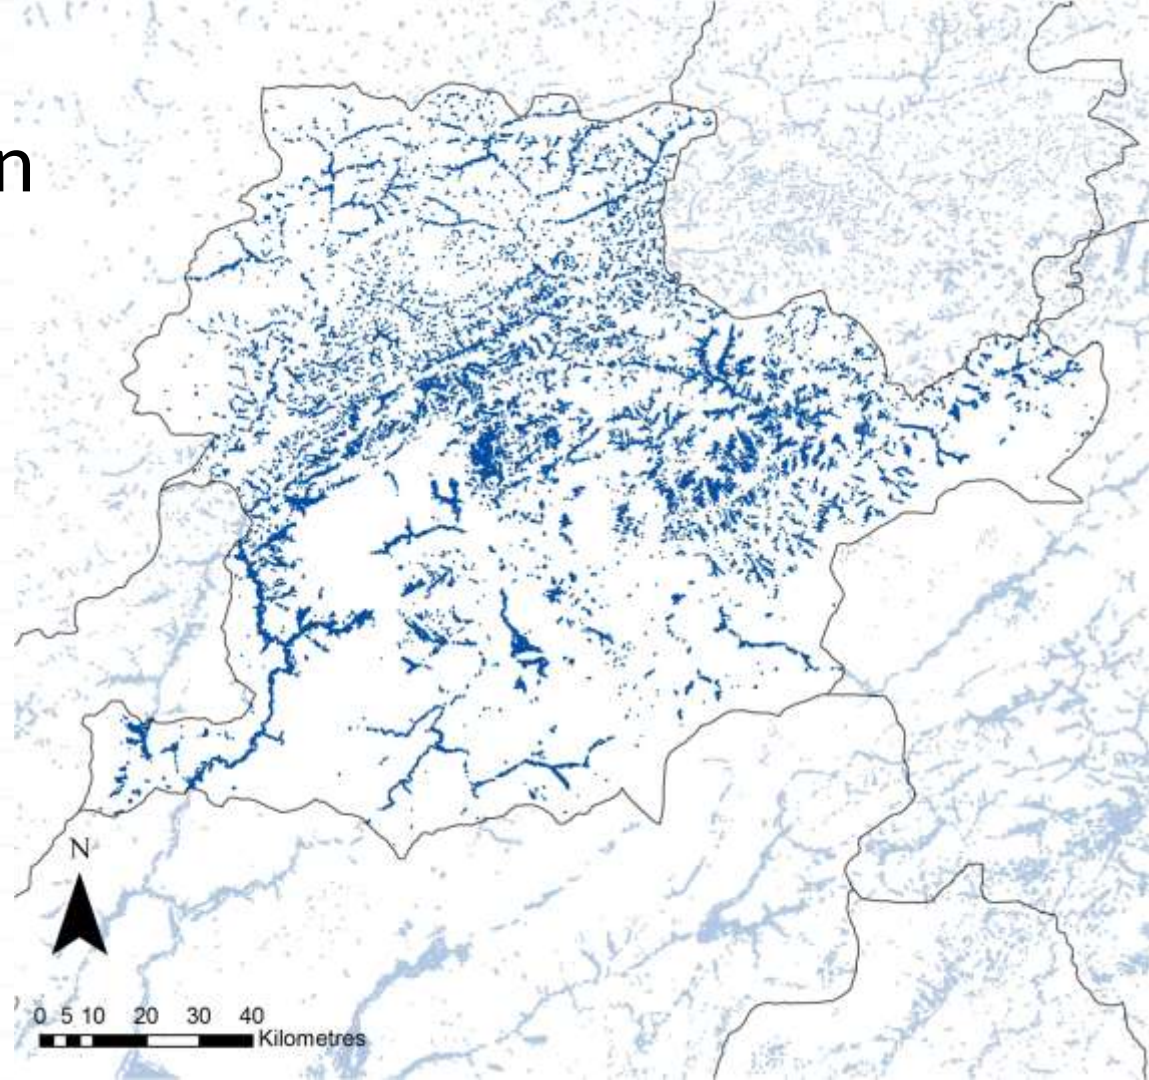

Outputs: EA level uncertainties

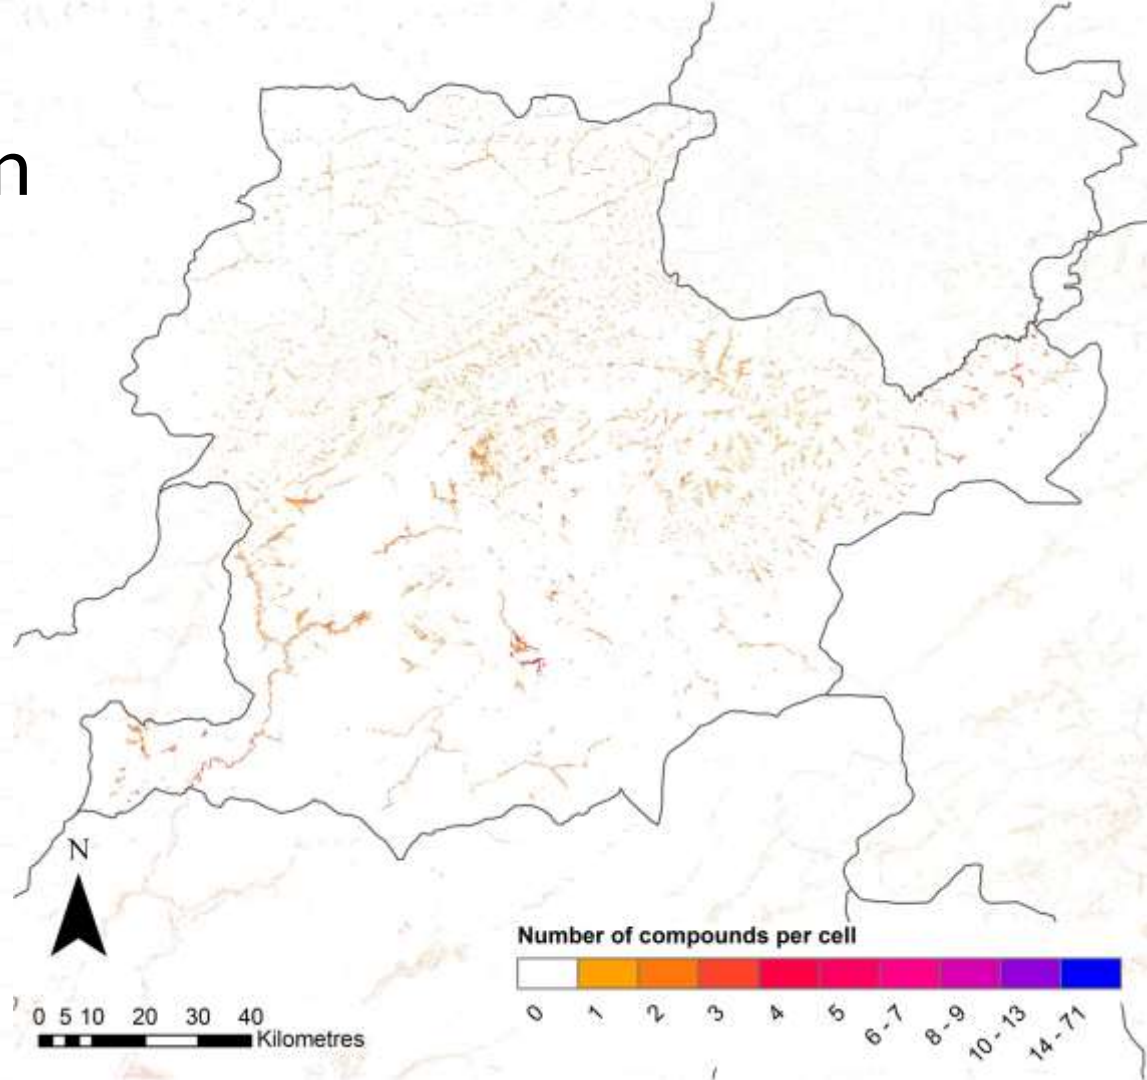

Spatial disaggregation to 100x100m cells

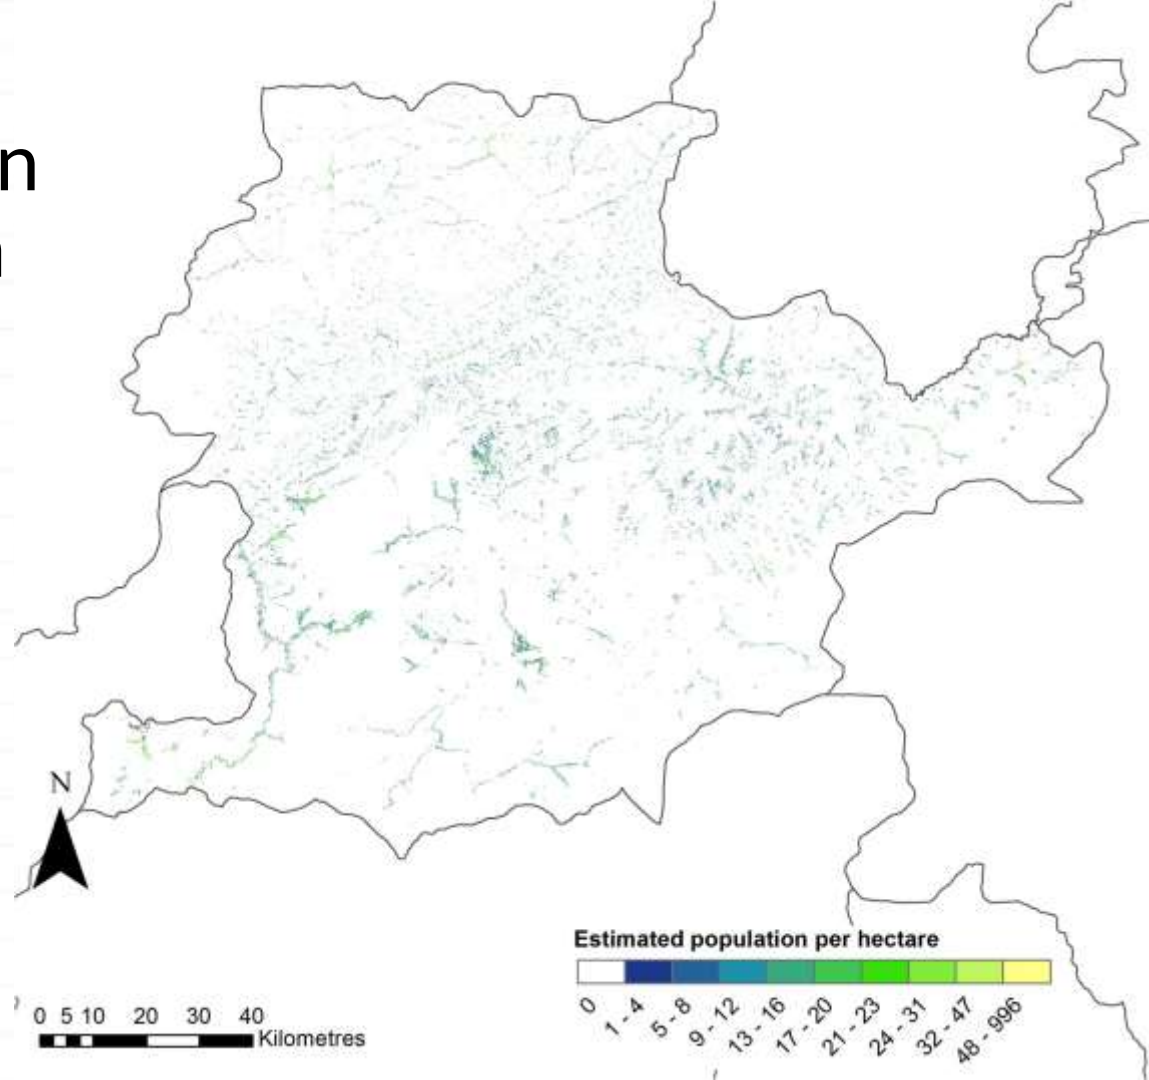

Spatial disaggregation to 100x100m cells

Spatial disaggregation to 100x100m cells

Spatial disaggregation to 100x100m cells

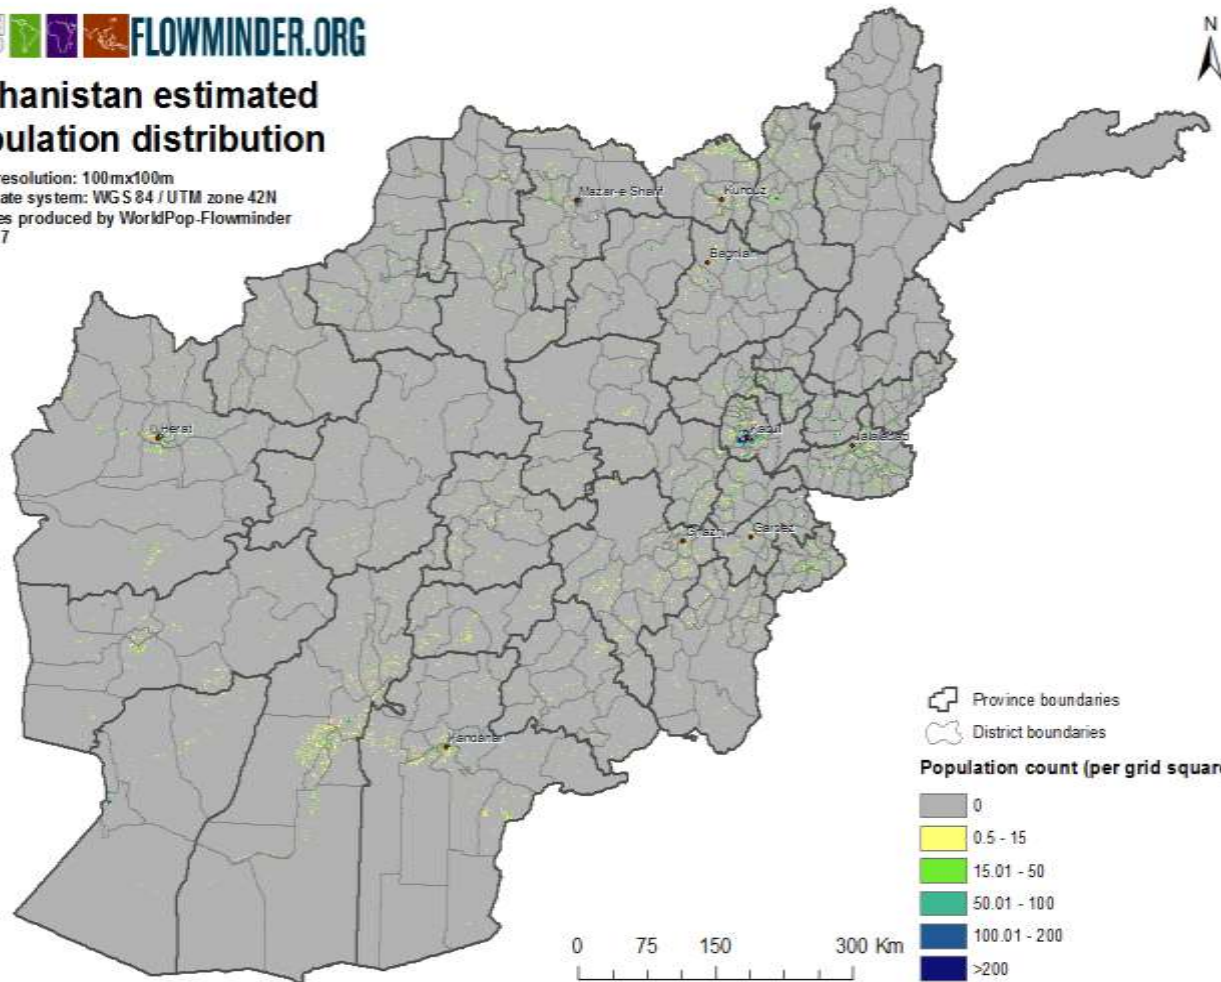

Afghanistan estimated population distribution

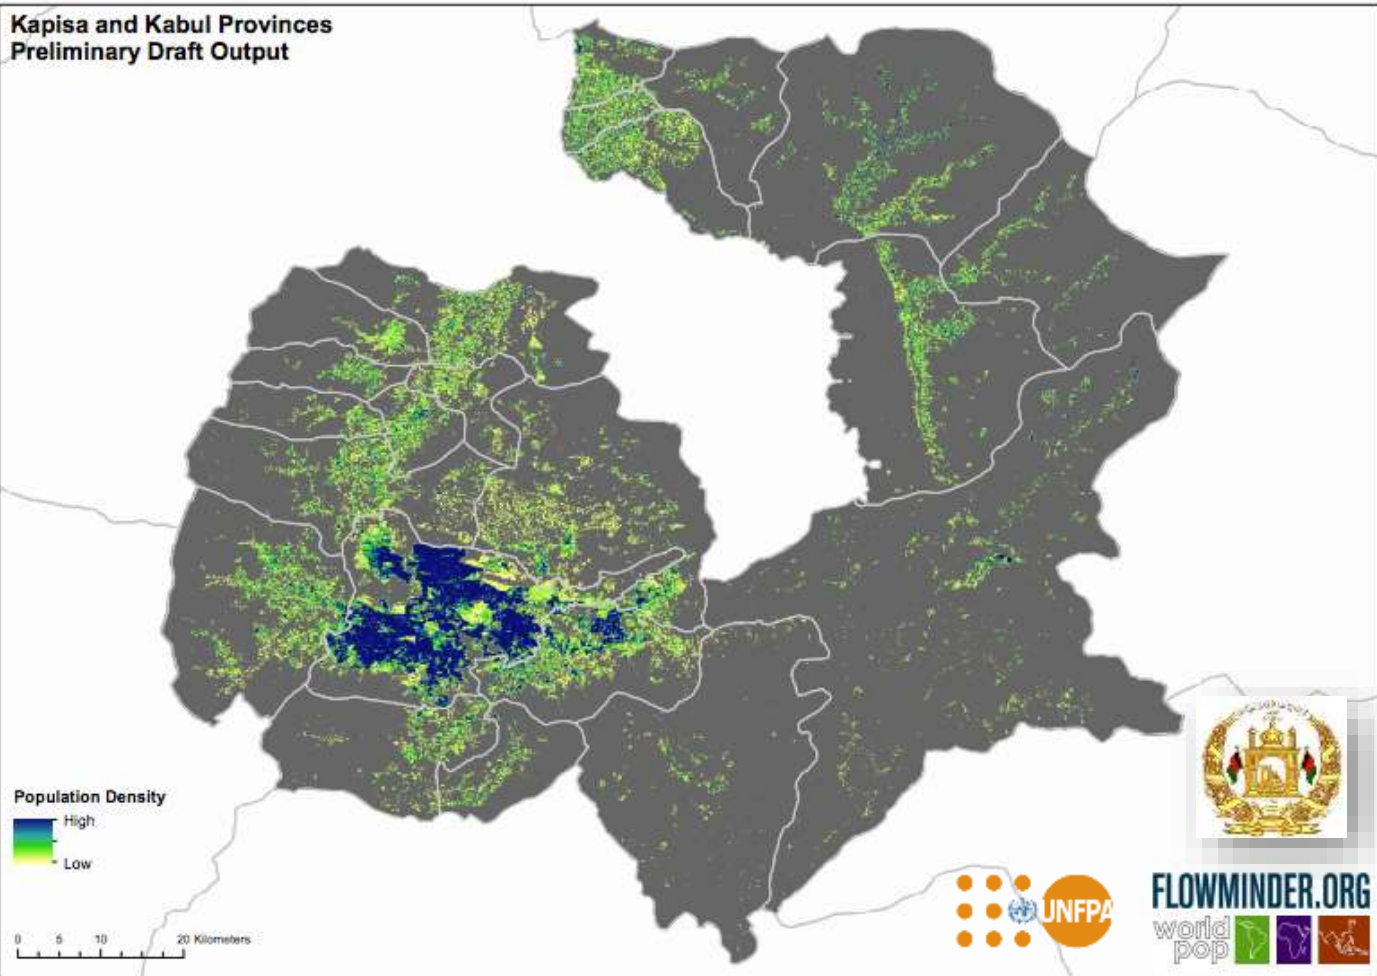

Spatial resolution: 100mx100m

Coordinate system: WGS 84 / UTM zone 42N

Estimates produced by WorldPop-Flowminder
July 2017

Kapisa and Kabul Provinces Preliminary Draft Output

Modelling population pyramids

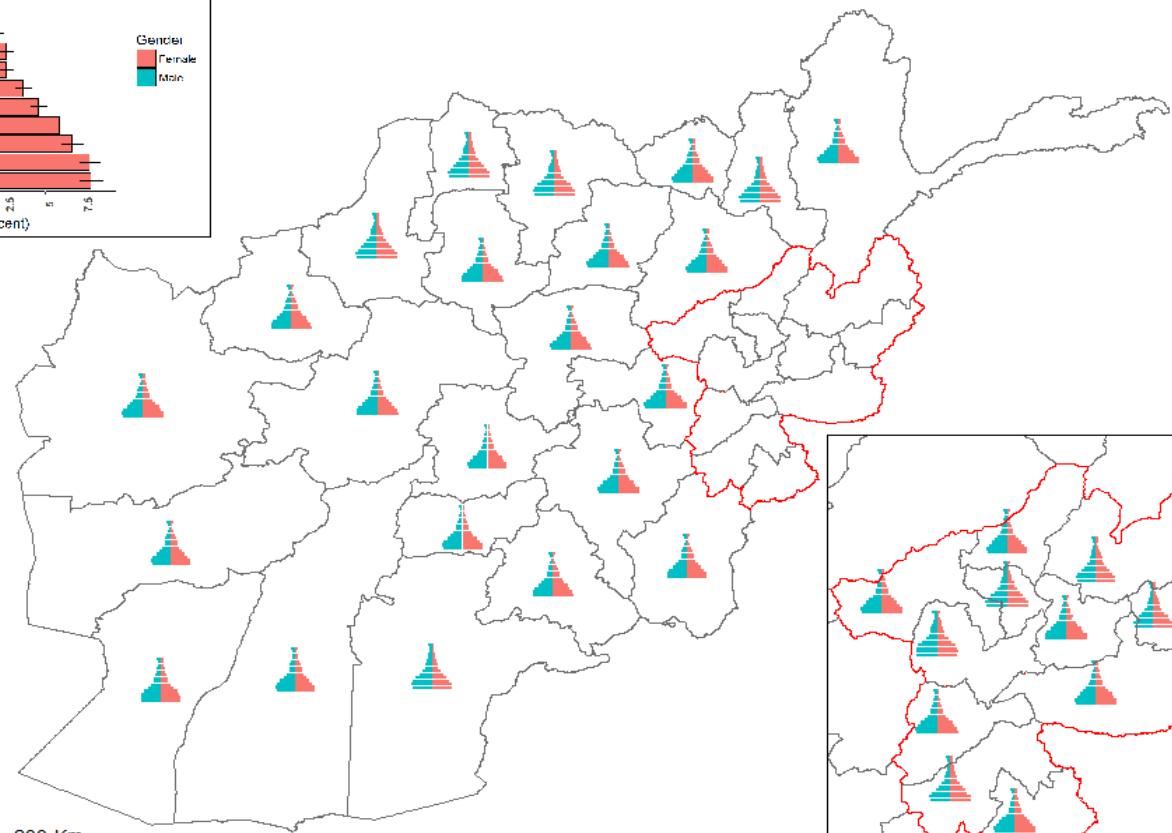

Age/sex structure cross-validation

EA: R-square = 0.80
District: R-square = 0.89
Province: R-square = 0.97

Province boundaries

Key considerations

- Uncertainties are substantially higher in unsampled locations
- Uncertainties are higher for predictions made at fine spatial scales
- Mobile populations are not explicitly accounted for
- Estimates can be improved further with new survey and geospatial data

DÉFINITION

Le Recensement Général de la Population et de l'Habitation est une opération d'enquête nationale qui vise à fournir des informations d'ordre

[Lire la suite >](#)

OBJECTIFS

- Disposer d'informations détaillées et exhaustives sur la population et l'habitation;
- Disposer d'une répartition par unité administrative

[Lire la suite >](#)

RÉSULTATS ATTENDUS

- 1- l'effectif global de la population, sa structure par sexe et par âge, et sa répartition spatiale selon les différentes unités administratives et le milieu de résidence ainsi que son évolution suré connus ;

INFORMACIÓN PARA TODOS

4. Imputación en Rutas: Modelo jerárquico usando inferencia Bayesiana

JAGS

- Personas por vivienda en la unidad
 - Densidad de instituciones educativas
 - Índice de hogar pobre
- Total de unidades de vivienda
 - Distancia al centro
 - Intensidad de luz
- Es escuela o no
 - Educación
 - Luces nocturnas
- Se encuentra o no edificación
 - Densidad de edificaciones

Estimación de las personas en unidades de tipos

Census process support: Use of census cartography

- Population counts are collected in census preparation phases – e.g. cartography – but can often be incomplete
- Value in having full coverage of recent estimated population for planning the full census
- Bottom-up estimation for under-enumerated units, followed by top-down disaggregation to grid squares

Census cartography: Mali

- Bottom-up model fitted using the population counts of the 25,466 enumeration areas fully covered by the census cartography
- Top-down model used to map enumeration area total to 100x100m grid square estimates

Questions?

To think about (as you listen to case studies):

-Do the case studies presented have similarities to your own situations?

-If you see a need for it in your country, what types of population data might be available to support bottom-up estimation modelling?
